Marketing Ambitions and Empirical Realities: Analyzing Research on AI Capabilities Across Domains

In 2021, I began studying machine learning. I had just read an article about how single board computers were being used in robotics along with python and could handle small self-managing tasks, like walking, navigating terrain, and operating arms. As a software engineer specializing in accessibility, I was interested in how machine learning and AI could be used in assistive technology. Single board computers were out of stock across the United States, so I was not able to pursue my experiments (but I did learn python) and in November of 2022, OpenAI would launch ChatGPT, bringing generative AI to the wider public. (Roose, 2022)

AI in Context

GenerativeAI (genAI) is only one type of artificial intelligence, of which there are many. The other type of artificial intelligence relevant to this review are convolutional neural networks (CNNs). Convolutional neural networks are typically used for classification and vision tasks and are a type of neural network, a subset of machine learning essential to deep learning (IBM, n.d), algorithms modeled after the way humans make decisions and learn. GenAI is a machine learning model that relies on deep learning models and can create original content, including text, images, and sound. (IBM, n.d)

While the focus of CNNs tends to be narrowly defined and specific, genAI tends to be more

broadly tasked, expected to be capable of anything according to the companies that market them.

Since the marketing of CNNs and genAIs models are different, it is important for decision makers at businesses, agencies, organizations and especially policy writers at businesses and regulatory bodies to be aware of the realistic capabilities of these models before committing their employees, business models, regulations, laws, or other decisions to their capabilities. As a software engineer and a marketer, I am aware of how, especially in the technology industry, marketing is based on promises of future products and services that have not been created or developed yet and often take years to be delivered if they ever are – an industry that embraces the spirit of “move fast and break things.” (Baer, 2014)

With OpenAI’s release of ChatGPT in 2022 followed by Google’s release of Gemini, Bard, and Duet AI, and Anthropic’s Claude, companies are integrating genAI into all of their current offerings and developing ways to replace or minimize human workers. Conversely, studies show that CNNs perform exceptionally well in the healthcare industry, reducing human error, saving labor hours, and allowing expert knowledge workers to focus their time on human connection work instead.

Research Question and Scope

I will be addressing the specific question of “How does current research characterize the gap between AI marketing claims and the demonstrated ability of AI across different domains?” and will be consulting with resources from diverse fields, including computer science and AI, business ethics, marketing, economics, sociology, medical technology and healthcare, labor studies, organizational behavior, science and

technological studies, and science and technological studies (specifically, the advertising of).

AI in Healthcare

Eric Topol is a cardiologist, executive vice president of Scripps Research, founder of Lerner College of Medicine at the Cleveland Clinic in Cleveland, OH, and primarily focuses his research on “individualized medicine using genomic, digital, and A.I. tools.” (Topol, 2025) In his book, *Deep Medicine* (2019), Chapter 6: Doctors and Patterns focuses on what he considers “patterns-centric” applications in the medical field. This would be a type of diagnostics that relies on scans or slides, including radiology, pathology, and dermatology.

CNNs are typically narrowly focused and trained on a specific task and because they are ideal for classification and visual inputs, they can be trained for visual pattern recognition tasks. In the healthcare field, different models have been developed to assist in fields such as radiology, pathology, and dermatology. These fields typically require highly paid, expert medical professionals to focus for long hours day after day to examine image after image, where they can be expected to review over 20,000 studies a year without ever interacting directly with a patient (Topol, 2019) Even so, some studies suggest that false negative rates among radiologists could be over 25% and 31% of American radiologists have experienced a malpractice claim.

Conversely, a specially trained CNN was able to diagnose hip fractures with 99% accuracy from x-rays alone when typically, more expensive testing was required for human radiologists to make a definitive diagnosis. (Topol, 2019). CNNs also achieved higher

accuracy rates than human pathologists and dermatologists in similar tests (Topol, 2019). While Andrew Ng tweeted “We can now diagnose pneumonia from chest x-ray better than radiologists.” in 2017 after a test where they found their algorithm “exceeds average radiologist performance on pneumonia detection”, there were doubts and questions about their methodology. However, in a more careful study from 2018, a CNN was able to classify chest x-rays as either normal or abnormal with 95% accuracy. (Topol, 2019) While this CNN would not be providing a diagnosis on its own, it would be saving a radiologist a tremendous amount of time to focus on abnormal x-rays.

Interestingly, in Cory Doctorow’s article “AI Can’t Do Your Job” he used the example of AI assisting radiology departments in their work as a cautionary tale. Cory Doctorow is an author, activist, and journalist who works for the Electronic Frontier Foundation, is an MIT Media Lab Research Affiliate, and a Visiting Professor of Computer Science at Open University and co-founded the UK Open Rights Group. Automation theory calls this a “centaur” - a human intelligence piloting a tireless machine body. (Doctorow, 2025) While a “centaur” dynamic could work the way Topol theorizes, Doctorow claims the real marketing pitch is a “reverse-centaur” - a “human who acts as an assistant to a robot.” AI companies are selling their solutions as a way to eliminate the majority of radiology positions, as an example, and replace them with CNNs under a radiologist’s supervision and this lone radiologist can ensure that the AI doesn’t make any errors. The radiologist is there to take the “blame” for AI errors, working hours that are just as long and having to be just as diligent as they are now, if not more so. (Doctorow, 2025).

Marketing Claims: The Ambitious Promises of Generative AI

"OpenAI's mission is to ensure that artificial general intelligence (AGI)—by which we mean highly autonomous systems that outperform humans at most economically valuable work—benefits all of humanity." (OpenAI, n.d.) While AGI and genAI are not the same thing, the current most well-known companies (OpenAI, Anthropic, Alphabet (Google), Microsoft, Meta, xAI, Synthesia, etc) are racing to achieve AGI which they measure by its ability to outperform humans at most economically valuable work – something that marketers are already claiming that genAI can do in regards to knowledge work.

GenAI is marketed to businesses as a way to replace knowledge workers the way that machines replaced manual laborers in factories during the industrial revolution. (Crawford, 2021) According to "The Generative AI Dossier" from Deloitte (2023), a professional services network that provides consulting, auditing, and other services to businesses globally, Generative AI can provide marketing content, product design, virtual models (still images or video), software development, customer support, market research, occupational health and safety training materials, market analysis, corporate risk management, simulated urban planning, searching policy documents, drafting contracts and proposals, onboarding caseworkers, and language translation. Deloitte states "One of the primary differences between more traditional AI and generative AI is that the latter can create novel output that appears to be generated by humans." Deloitte goes on to list six "key modalities" that, according to them, GenAI can generate: text, code, audio, images, video, 3D objects. (Deloitte, 2023)

On OpenAI's Enterprise site, they claim that ChatGPT can "generate better code, craft emails, analyze data" and act as a "superassistant for every member of your team."

Google advertises Gemini as “your always-on AI assistant,” can be integrated into every Google service, and can be your research analyst, sales associate, productivity partner, creative assistant, and meeting note taker. Google also claims that Gemini can generate marketing campaign briefs, project plans, and presentations as well as create sales pitch materials.

Microsoft has also integrated Copilot into all their services and on their website for business customers claim it can summarize your emails, draft your emails for you, summarize your meetings, calls, and chats and provide insights, create branded presentations, track your employee's activity, and track non-compliant use of company data.

The Evidence Gap: Comparing Performance to Promises

Armin Alimardani, a lecturer in Law and Emerging Technologies at the School of Law at the University of Wollongong in Australia frequently publishes research on the social, ethical, and legal impact of technology, including artificial intelligence and is a consultant for OpenAI. In response to claims made by OpenAI that ChatGPT achieved a “score of 289 out of 400 in the US Uniform Bar Examination,” a study by Armin Alimardani in 2024 compared the scores of 10 genAI generated papers scores for a ‘Criminal Law’ final exam for an Australian law school in spring of 2023 and compared them to the scores of student responses. He found that the scorers, unaware of genAI involvement, scored below the student average on questions that involved detail legal and critical analysis but better on open-ended questions and essay writing tasks. (Alimardani, 2024). The tutors were not

able to tell which tests were AI and which ones were not. Alimardani concluded that the various genAI models that were tested (OpenAI's 4-Frontend, 3.5-Frontend, GPT-4-1106 backend, Google Bard, and Microsoft Bing) performed well in short answer and short essay questions, they did not perform as well in scenarios that involved more realistic levels of complexity. (Alimardani, 2024)

According to an article by Plamen Chamurliyski (2023), a student at the University of Shumen in Bulgaria, when using ChatGPT 3.5 (the free version) to write a scientific article, the tool was fast and easy to use, but it couldn't accurately interpret the results of the scientific study to be written about, didn't always understand what it was being asked, and required some technical knowledge in order to generate graphs and tables. While it helped reduce the time in writing the paper for this case, it did not perform flawlessly.

I was able to find information confirming that various genAI models could complete tasks like those listed in The Generative AI Dossier (Deloitte, 2023), it was difficult to find discussion on how well genAI completed those tasks and how much time it saved workers. While I found copious amounts of the equivalent information regarding CNNs and healthcare (Zebra Medical Vision analyzed scans at a speed almost 10,000 times greater than radiologists at a cost of one dollar per scan, Topol 2019), I have been unable to find similar empirical evidence regarding productivity gains or reductions regarding marketing, data analysis, software development, customer service, or other fields where genAI is commonly deployed. Deloitte, Alimardani, Chamurliyski, OpenAI, Anthropic, Google, Microsoft, and Meta also caution that genAI is prone to errors, but I could not find data on

how frequently errors occurred, though those errors may include out of date information, misinterpreted information, or fabrications (known as “hallucinations,” Deloitte 2023).

Broader Implications: AI, Automation, and the Changing Labor Landscape

M.Y. Mohammed and M.J. Skibniewski examine the role of AI in the workplace in their paper, “The Role of Generative AI in Managing Industry Projects: Transforming Industry 4.0 Into Industry 5.0 Driven Economy” while Kate Crawford examines the role of AI in the traditional models of capitalist/employee relationships in her book, *Atlas of AI* (2023) in Chapter 2: Labor.

M.J. Skibniewski is a professor of Civil and Environmental Engineering at the University of Maryland, writes frequently on the topics of constructing engineering and management, automation and robotics, information technologies for project management, and infrastructure resilience and sustainability, who published this paper in partnership with his student, M.Y. Mohammed.

Kate Crawford is a research professor at USC Annenberg in Los Angeles, a Senior Principal Researcher at MSR in New York and leads the Knowing Machines Project, a research collaboration of scientists, artists and legal scholars investigating how AI systems are trained, and she has advised policy makers in the United Nations, White House, and European Parliament.

The Distributed Artificial Intelligence Research Institute are working for a more inclusive, less exploitative, healthier, more community focused approach to the development and research of artificial intelligence that focuses on community care and

improvements as a goal rather than artificial intelligence as a goal unto itself. It promotes artificial intelligence as one possible goal rather than an inevitability or singular solution. It was established in 2021 by Timnit Gebru as “an independent, community-rooted institute set to counter Big Tech’s pervasive influence on the research, development, and deployment of AI.” (DAIR, n.d.)

Adrienne Williams is an educator and research fellow at Just Tech and the Distributed Artificial Intelligence Research institute who previously worked for Amazon as a delivery driver and organizer, experiencing the effects of Amazon’s worker surveillance and quota systems hand. Milagros Miceli is a sociologist, computer scientist and researcher who works closely with data workers globally and is the research lead at the Distributed Artificial Intelligence Research Institute and the principal investigator at the Data Workers Inquiry project. Timnit is an AI researcher and computer scientist and former co-lead of Google’s Ethical Artificial Intelligence team as well as the founder of Black in AI and the Distributed Artificial Intelligence Research Institute.

Historically, companies have been invested in maximizing profits for their owners, investors and shareholders – their interest in AI as a result is not on making their employee’s job easier, less stressful, and reducing the more mindless and repetitive aspects of their work, but rather in increasing efficiency, cutting costs, and increasing profits. (Crawford, 2023) A study by Daron Acemoglu and Pascual Restrepo, Professor of Economics at the Massachusetts Institute of Technology and Assistant Professor of Economics at Boston University respectively, of markets in the US found that, unlike Europe, the introduction of automation does lead to job loss of about 6 jobs per robot.

While they estimated only 360,000 – 670,000 jobs were lost this way, according to the US Bureau of Labor Statistics 4.8 million new jobs were added in the US in 2017-2018.

(Mohammed & Skibniewski, 2023) While this may seem to offset jobs loss to automation, 94% of jobs created between 2005 and 2015 were for “alternative jobs” - jobs that are not full-time, salaried work, including temporary positions, on-call workers, contract workers, independent contractors, freelancers, and gig/app workers. People are working longer hours at more jobs for less pay, without any benefits or stability. (Crawford, 2023).

Mechanical Turk is an example of the type of gig/app work that Crawford referred to as “alternative” jobs that were created as replacements for the jobs lost to automation. The Mechanical Turk is a fraudulent chess-playing machine constructed in 1770 that appeared to be able to play chess but in actuality was operated by a human chess player hidden inside and is the name that Amazon gave its “crowd sourced” “artificial intelligence” service, where workers can accept tasks from requesters and receive payment on a per task basis. This service was used to train the image dataset for ImageNet in 2009, reviving research into artificial intelligence after interest had waned and has been used repeatedly to train further datasets, for only a few cents per task. (Williams et al, 2022)

Other examples of these “new opportunities” in gig work include content moderators who work on social media platforms and flag or remove inappropriate content such as hate speech, misinformation, violence, and sexual content, which also serves to further train those platform’s AI moderation systems. These jobs typically pay a couple dollars an hour, even when they aren’t outsourced to third world countries, and are deeply

traumatic and workers are simultaneously monitored by surveillance software to ensure productivity. (Williams et al, 2022).

The effectiveness of marketing has caused some startups to hire people to impersonate AI systems like chatbots and a venture capital firm, MMC Ventures, found that 40% of AI startups in the EU didn't use AI in a meaningful way. (Williams et al, 2022).

Conclusions and Recommendations for Decision Makers

In a recent post on Reddit, a pseudonymous user claiming to be an accountant posted complaining about OpenAI's ChatGPT, saying "I'm so fucking over my boss saying 'chatgpt says to...' It's not accurate. It's not a source of truth. If you want something done, just tell me. I'll make it happen in a logical and appropriate way." The user also commented that they had been seeking a new position for over a year. The thread as of this writing has 4.6k upvotes and 237 comments, primarily from other users sharing similar stories and sympathizing with the original poster. (InterestingBrother31, 2025)

While companies are rapidly adopting AI to replace their expert knowledge workers, they risk their institutional knowledge and important domain knowledge, including legal compliance, cybersecurity and data practices, worker protections, and more. The marketing of genAI, while espousing the many benefits and tasks that models can accomplish, still cautions that mistakes can and do happen whereas in healthcare, studies are rigorous and carefully evaluated. This should not be the only field where studies are taking place.

Companies should consult with their knowledge workers, who are already the experts in their fields, about how genAI could help them in their work and then, after adoption, ask them about their experience. Tracking metrics in a non-punitive way, similar to CNNs in healthcare, is a reliable method of deciding if genAI is contributing to your company goals. GenAI is better at shorter, less complex tasks, so it may be a valuable tool to relieve employees of simplistic, repetitive tasks and allowing them to focus on more complex tasks.

Research and controlled studies, similar to what has been conducted with CNNs in healthcare, should be conducted to know the true benefits of genAI in the workplace. Long term studies around institutional knowledge, critical thinking, and expertise would also be beneficial. (Crawford, 2023). Decision makers, both in business and policy, should demand empirical evidence of productivity before accepting claims from companies seeking to make profit from their organizations. Seeking out and consulting with workers, small-business owners, and educators to discover how the saturation of genAI has affected their environments – not just in regard to work and social behaviors, but also in terms of cost and risk is recommended. Policy makers, especially, should be cognizant of the potential effect, long- and short-term, on the labor markets and communities – not just in Western countries, but around the globe as well. (Crawford, 2023, Mohammed & Skibniewski, 2023)

Annotated Bibliography

Topal, Eric. (2019). Doctors and Patterns. Deep Medicine: How Artificial Intelligence Can Make Healthcare Human Again. Basic Books.

Written in 2019 when CNNs were available but before the release of generative AI to the public, Eric Topal, cardiologist and research scientist, writes about the development of AI and its use both inside and outside of the medical field and the potential applications of that technology in the future. Topol uses his own firsthand experiences as examples to provide a narrative to the studies and statistics presented throughout his book.

Chapter 6, Doctors and Patterns' focuses on a type of medical practice Topol refers to as "pattern-centric" practices that involve scans or slides, making an assessment and formulating a plan. He interprets this as a very data-heavy style of medical practice, focused on objective information and analysis to come to a solution. This style of medical practice is more accessible to narrowly trained or "niche" style CNNs that are trained on very specific sets of data for specific tasks and, as such, can be trained to a high degree of accuracy and efficiency.

While Deep Medicine is rich with studies and statistics, this chapter is ideal for demonstrating the rigor of testing that AI models can go through and as such I have chosen to include it in this review.

Crawford, K. (2021). *Labor. Atlas of AI: power, politics, and the planetary costs of artificial intelligence*. Yale University Press.

Issues in technology are fixed by applying technological solutions, and Kate Crawford illustrates how these neglect social, humanitarian, labor rights, climate issues, and more. She examines artificial intelligence and marketing around it in the context of a larger society and asks what artificial intelligence really is and what it can offer us as in both a local and a global society.

In Chapter 2, 'Labor', Crawford focuses on different theories of productivity, capitalism, and labor and the history of the effect of efficiencies and automations on the labor market to project what we can expect from the introduction of AI along with the current speculation among the investor class.

Crawford approaches her topics in a frank and unvarnished matter. Those familiar with economics will find theories here familiar and simply applied to AI in a practical and straightforward way. The writing is clear and easy to understand, and speculation is kept to a minimum while focus is kept primarily on historical events and studies.

Mohammed, Moyasser Y and Mirosław J Skibniewski. "The Role of generative AI in Managing Industry Projects: Transforming Industry 4.0 Into Industry 5.0 Driven Economy." *Law and Business*, vol 3, no 1, January 2023, pp 27 – 41, <https://doi.org/10.2478/law-2023-0006>.

Mohammed and Skibniewski examine the studies that examine returns in productivity from introducing several types of automated workers (robots, generative artificial intelligence, chatbots, etc.) in workplaces in both Europe and the United States and investigate the differences between results. They also investigate issues introduced by the introduction of automated workers as well as the arguments for and against doing so from a variety of different stakeholders and perspectives.

They also examine specific claims that genAI can fulfill specific tasks associated with task management and test those claims for themselves to see if those tasks can be fulfilled.

Their results are clear, well-articulated, and easy to understand, and references are well-sourced.

Deloitte AI Institute. (2023) The Generative AI Dossier.

<https://www2.deloitte.com/content/dam/Deloitte/us/Documents/consulting/us-ai-institute-gen-ai-use-cases.pdf>

The Deloitte AI Institute is a part of the larger Deloitte organization, a private professional services network known for consulting, audit, and tax advisory Services to some of the largest corporations and companies and is committed to connecting companies with AI solutions.

The Generative AI Dossier is a guide to introduce organizations to generative AI and what it can be used for in their companies, exploring the areas of consumer services, energy, resources, and industrial, financial

services, government and public services, life sciences and health care, and technology, media, and telecommunications. For each use case, they offer solutions and risks to watch out for as well as tips on how to utilize each function in your business.

This is a standard representation of marketing materials regarding AI services and solutions.

Sira, M. Generative AI Takes Centre Stage: Revolutionizing Productivity and Reshaping Industries. *System Safety: Human - Technical Facility - Environment*, 2023, Sciendo, vol. 5 no. 1, pp. 57-65. <https://doi.org/10.2478/czoto-2023-0007>

Mariya Sira examines the way that generative AI can be used for productivity according to the claims of both researchers and the companies developing generative AI models. This is a high-level survey of the diverse ways that generative AI can be used without testing or investigating its efficacy.

Sira primarily utilizes literatures reviews, content analysis, and synthesis arriving at her conclusions and also utilizes *The Generative AI Dossier*. She does not test the veracity of the claims but does organize them by industry.

Chamurliyski, P. Enhancing efficiency in scientific writing in the field of plant growing:

Collaborating with AI assistant ChatGPT for enhanced productivity. *Acta Scientifica Naturalis*, 2023, Sciendo, vol. 10 no. 3, pp. 73-81. <https://doi.org/10.2478/asn-2023-0023>

Plamen Chamurliyski was, at the time, a student at the University of Shumen in Bulgaria and was exploring the experience of utilizing ChatGPT by OpenAI as a tool in writing a scientific publication.

The resulting paper describes his experience step-by-step through recreating a paper written by Chamurliyski, P., Penchev, E., & Tsenov, N. on the Productivity and stability of the yield for common wheat cultivars developed at IPGR (Institute of Plant Genetic Resources). It concludes with a description of his subjective experience using ChatGPT, including the advantages and disadvantages of doing so.

This paper is an accurate demonstration of prompting ChatGPT to generate an article or paper quickly from supplied data and notes the user has available.

Alimardani, A. (2024) “Generative artificial intelligence vs. Law students: an empirical study on criminal law exam performance,” *Law, Innovation and Technology*, 16(2), pp. 777-819. Available at: <https://doi.org/10.1080/17579961.2024.2392932>

Dr Armin Alimardani is a lecturer in Law and Emerging Technologies at the University of Wollongong Australia and at the time of this article disclosed that he had a short-term, part-time contract with OpenAI as a consultant who had not funded this research or article.

This article describes an experiment where law tutors compare and score tests by a variety of genAI models and students unaware so that comparisons between models and students can be made in reference to

claims by OpenAI. After comparisons, the tutors are asked if they could tell which papers were written by the genAI models.

This was a well-detailed, thorough article informative of the strengths and weaknesses of different genAI models and how they compare to the average students work from someone who is an experienced expert.

Doctorow, C. (2025). AI Can't Do Your Job. Pluralistic Daily Links from Cory Doctorow.

<https://pluralistic.net/2025/03/18/asbestos-in-the-walls/#government-by-spicy-autocomplete>

Cory Doctorow is a science fiction author, activist, and journalist who works for the Electronic Frontier Foundation, is an MIT Media Lab Research Affiliate, a Visiting Professor of Computer Science at Open University, a Visiting Professor of Practice at the University of North Carolina's School of Library and Information Science, and he co-founded the UK Open Rights Group.

Known for writing daily on his blog, Doctorow is a passionate writing who believes in a technology that serves society for the greater good and uses his voice to fight against capitalist greed, the marketplace of private data sales, propaganda, and information warfare.

In this article, he writes about the deceptive practices that marketing has become known for and how they're currently being employed by the biggest AI companies to convince companies to replace employees with their products despite those products lack of fitness.

This is a passionate article written by someone extremely familiar with the topic.

Williams, A., M. Miceli, T. Gebru. (2022). The Exploited Labor Behind Artificial Intelligence: Supporting transnational worker organizing should be at the center of the fight for “ethical AI.” Noema (13 October), at <https://www.noemamag.com/the-exploited-labor-behind-artificial-intelligence/>, accessed April 11, 2025

Adrienne Williams, Milagros Miceli, and Timnit Gebru are from the Distributed Artificial Intelligence Research Institute, and institute committed to countering exploitation in artificial intelligence development and research, centering diverse communities, and focusing on worker and laborer’s health and rights. Research materials and initiatives focus on artificial intelligence companies’ harm to communities and workers and deceptive practices.

Adrienne Williams formerly worked for Amazon as a delivery driver and labor organizer, while Milagros Miceli has experience as a sociologist and data researcher. Timnit Gebru is a computer scientist and AI Ethicist who formally co-led Google’s Ethical Artificial Intelligence team.

It should be noted that they are all women of color writing in a field dominated by white men.
